 Main Question
 Reductive groups

 Modular compactifications
 Review: Toric varieties

 Symplectic cutting
 Review: Wonderful compactifications of adjoint groups

Let *G* be (connected) split reductive group over a field (i.e. over \mathbb{C} , $G = K_{\mathbb{C}}$, with *K* compact Lie group)

e.g. G =semi-simple, $GL(n, \mathbb{C}), (\mathbb{C}^*)^n, \operatorname{Spin}_{\mathbb{C}}^c, \ldots$

e.g. G =semi-simple, $GL(n, \mathbb{C}), (\mathbb{C}^*)^n, Spin_{\mathbb{C}}^c, \dots$

Question

What are 'good' compactifications \overline{G} of G?

Here 'good' should mean

- G × G-equivariant
- smooth, with all orbit closures smooth
- boundary $\overline{G} \setminus G$ is a smooth normal crossing divisor
- nice enumeration of orbits

くロト (過) (目) (日)

Reductive groups Review: Toric varieties Review: Wonderful compactifications of adjoint groups

Ideally want some conceptual understanding of boundary $\overline{G} \setminus G$

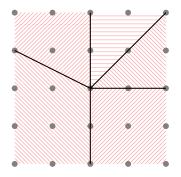

modular compactification?

Reductive groups Review: Toric varieties Review: Wonderful compactifications of adjoint groups

Toric varieties & fans

Toric varieties \overline{T} are normal *T*-equivariant varieties with open dense orbit

Determined by fans: collection of strongly convex, rational cones in $\Lambda_{\mathcal{T}}\otimes_{\mathbb{Z}}\mathbb{Q}$

- every cone simplicial ⇒ at worst finite quotient singularities
- non-minimal element on ray ⇒ extra orbifold-structure

イロト イポト イヨト イヨト

• fan complete $\Rightarrow \overline{T}$ compact

Reductive groups Review: Toric varieties Review: Wonderful compactifications of adjoint groups

Wonderful compactification

Definition (De Concini - Procesi)

The wonderful compactification \overline{G}^{w} of an adjoint group is the closure in $\mathbb{P}(\text{End}(V_{\lambda}))$

Independent of choice of λ

イロト イポト イヨト イヨト

Reductive groups Review: Toric varieties Review: Wonderful compactifications of adjoint groups

Wonderful compactification

Definition (De Concini - Procesi)

The wonderful compactification \overline{G}^{w} of an adjoint group is the closure in $\mathbb{P}(\text{End}(V_{\lambda}))$

Independent of choice of λ

 T_G maximal torus in G, take closure in \overline{G}^w \Rightarrow get toric variety $\overline{T_G}$

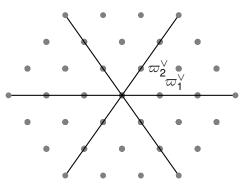

Fan of $\overline{T_G}$ = Weyl chambers + Λ_G

(Λ_G = co-weight lattice since *G* is adjoint)

 \mathbb{G}_m -equivariant *G*-principal bundles on chains of projective lines

Framed at north- and south-poles

Lenght of chain is arbitrary finite, can vary in families

Problem:

Too many objects: stack is not separated nor of finite type

Cure this by imposing a stability condition

Moduli problem Stability

Which bundles are stable?

Theorem (Birkhoff-Grothendieck-Harder)

Every *G*-principal bundle on \mathbb{P}^1 reduces to the maximal torus and up to isomorphims is entirely determined by a co-character

$$\Lambda \ni \rho : \mathbb{G}_m \to \boldsymbol{G}$$

unique up to W_G -action

Main Question Modular compactifications Symplectic cutting Symplectic cutting

Σ stacky fan, rays generate Λ over $\mathbb Q$ have

$$1 \to L \to (\mathbb{G}_m)^N \to T_\mathbb{C} \to 1$$

Theorem (Cox)

$$\mathcal{M}_T(\Sigma) \cong (\mathbb{A}^N)^0/L$$

If rays don't generate Λ, still have

$$\mathcal{M}_{T}(\Sigma) \cong \left((\mathbb{A}^{N})^{0} \times T_{\mathbb{C}} \right) / (\mathbb{G}_{m})^{N}$$

Want to generalize this to arbitrary groups
