## Introduction

The catchment of the Berze River is located in the central part of Latvia. The Berze River is a tributary of the Svete River, which further inflows into the Lielupe River. The length of the river is 117 km, the catchment area is 882.8 km<sup>2</sup>, the stream gradient is 1 m/km. The largest tributaries on the left bank are Bikstupe (32 km) and Licupe (14 km), while on the right bank Alave (24 km), Sesava (24 km) and Gardene (17 km). The hydrological regime of the river is affected by the dams constructed to ensure operation of four small hydroelectric power plants. The catchment is located in the Lielupe River basin district, which is designed according to the EU Water Framework Directive, the largest part of the catchment is located within the Nitrate Vulnerable Zones designed according to the EU Nitrates Directive. Water quality monitoring activities are carried out at 15 locations on a monthly basis using a grab sampling approach since 2005 thus representing water quality at 15 subbasins with different land use patterns (Figure 1). Water samples are analyzed in an accredited laboratory for nitrate nitrogen (NO<sub>3</sub>-N), ammonium nitrogen (NH<sub>4</sub>-N), total nitrogen (TN), orthophosphate phosphorus (PO<sub>4</sub>-P), and total phosphorus (TP) concentrations. One stream gauging station (Berze-Balozi) is located at the outlet of the Berze River, which provides the data on daily discharge.

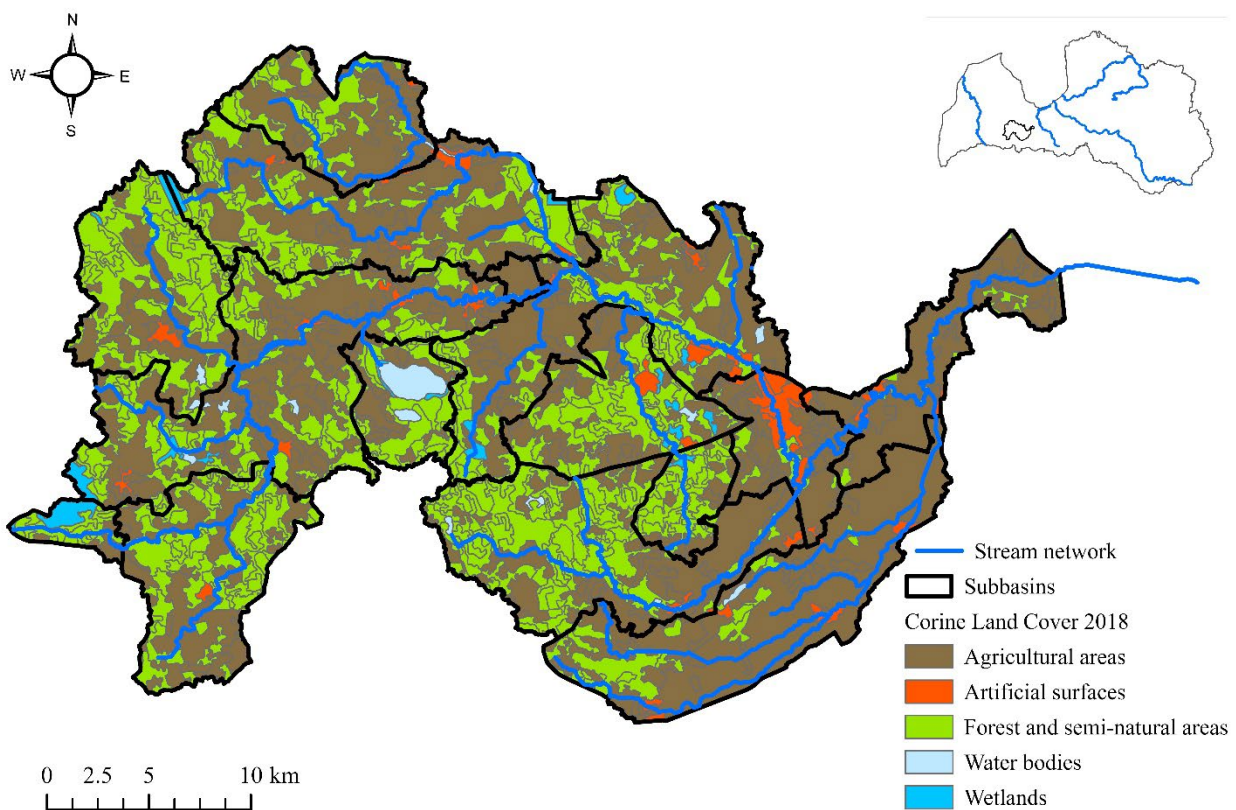

Figure 1. Subbasins, streams and land use of the Berze River catchment.

## Code versions used

| Code                           | Version number | Availability   |
|--------------------------------|----------------|--|
| QGIS                           | 3.28.2         | QGIS used as a basis for running the QSWAT+ plugin. In this project, the latest stable release was used, which is the version that QSWAT+ aims to be compatible with. This can be downloaded from: <a href="https://download.qgis.org/downloads/QGIS-OSGeo4W-3.28.2-1.msi">https://download.qgis.org/downloads/QGIS-OSGeo4W-3.28.2-1.msi</a> |
| SWAT+<br>(core model)          | 60.5.7         | Official code releases are available here: <a href="https://swatplus.gitbook.io/docs/installation">https://swatplus.gitbook.io/docs/installation</a>   |
| QSWAT+<br>(interface)          | 2.4.0          | Code and official installer releases are available here: <a href="https://swatplus.gitbook.io/docs/installation">https://swatplus.gitbook.io/docs/installation</a>   |
| SWAT+<br>Editor<br>(interface) | 2.3.0          | Code and official installer releases are available here: <a href="https://github.com/swat-model/swatplus-editor/releases">https://github.com/swat-model/swatplus-editor/releases</a>   |

## Weather input data used

| <b>Data</b>                  | <b>Temporal resolution</b>     | <b>Spatial resolution</b>  | <b>Availability</b>  |
|------------------------------|--------------------------------|--|--|
| Precipitation                | Hourly<br>(resampled to daily) | Provided from individual meteorological station located in the Dobele City | Provided by State Limited Liability Company "Latvian Environment, Geology and Meteorology Centre". |
| Min. and max air temperature | Hourly<br>(resampled to daily) | Provided from individual meteorological station located in the Dobele City | Provided by State Limited Liability Company "Latvian Environment, Geology and Meteorology Centre". |
| Relative humidity            | Hourly<br>(resampled to daily) | Provided from individual meteorological station located in the Dobele City | Provided by State Limited Liability Company "Latvian Environment, Geology and Meteorology Centre". |

## GIS input data used

| Data    | Map      | Resolution         | Availability  |
|---------|----------|--------------------|---|
| DEM     | DEM      | 5m raster          | Raster map from the national model with the resolution of 5x5 m.  |
| Landuse | Corine   | Vector (shapefile) | The CORINE Land Cover (CLC) inventory from 2018 was downloaded from <a href="https://land.copernicus.eu/en/products/corine-land-cover/clc2018">https://land.copernicus.eu/en/products/corine-land-cover/clc2018</a>                   |
| Landuse | Crops    | Vector (shapefile) | The map of agricultural field blocks provided by the Rural Support Service of the Republic of Latvia. The map was applied for determination of the share of crops in agricultural fields.   |
| Landuse | Drainage | Vector (shapefile) | The map of Digital Drainage Cadastre provided by State Limited Liability Company "Real Estates of Ministry of Agriculture". The map was applied for determination of the share of subsurface drainage systems in agricultural fields. |
| Soils   | Soils    | Vector (shapefile) | Vector map from the national model.   |
| Lakes   | Lakes    | Vector (shapefile) | Vector map provided by the State Limited Liability Company "Latvian Environment, Geology and Meteorology Centre".   |
| Rivers  | Rivers   | Vector (shapefile) | The map of Digital Drainage Cadastre provided by State Limited Liability Company "Real Estates of Ministry of Agriculture". The map was applied to represent the streams of national significance.                                    |
| Outlets | Outlets  | Vector (shapefile) | Manually marked considering the locations of water sampling sites.  |

## Stream discharge data used for calibration

| Data             | Temporal resolution | Spatial resolution                                    | Availability   |
|------------------|---------------------|---|--|
| Stream discharge | Daily               | Provided from individual gauge station (Berze-Balozi) | Provided by State Limited Liability Company "Latvian Environment, Geology and Meteorology Centre". |

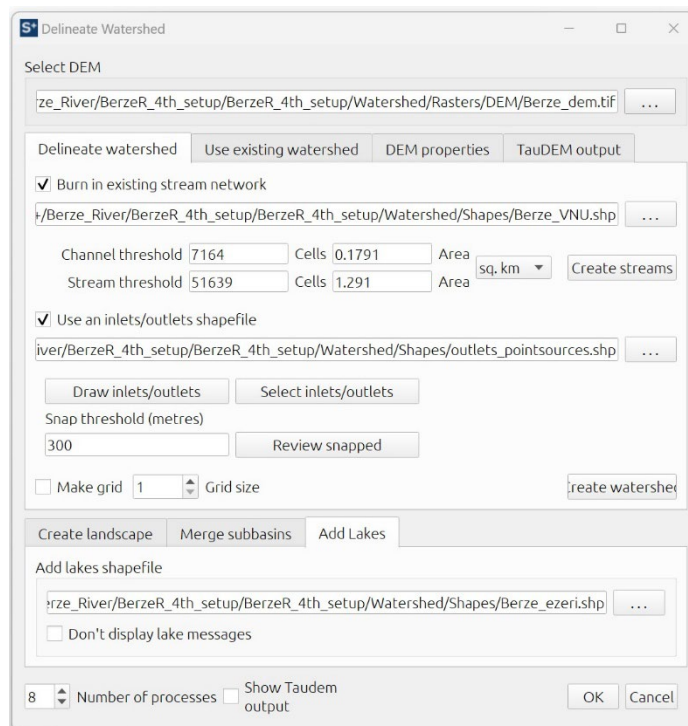

## Model setup

### Delineation

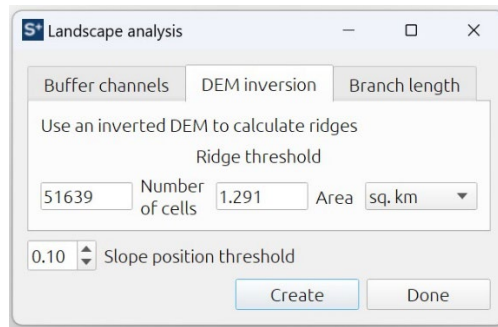

A detailed stream network was employed to refine channel and stream thresholds within the SWAT+ extension in QGIS ensuring a realistic stream network representation. Subsequently, the automatically delineated subbasins were merged to create 15 predefined subbasins representing the contributing areas and locations of water sampling sites, where water monitoring activities have been carried out in a long-term.

Channel threshold: 0.18 km<sup>2</sup> (minimum size of sub-watershed, and thereby a landscape unit (LSU), where a small channel that drains to a main stream is created)

Stream threshold: 1.29 km<sup>2</sup> (minimum size of sub-watershed, where a main stream is created). The existing streams of national significance were burned into the DEM layer to ensure representable generation of stream network:

Upslope/Floodplain LSUs: This is optional. This will divide each LandScape Unit (LSU) into an Upslope and a Floodplain LSU, and create individual aquifers per LSU (representing the Upslope and the Floodplain areas, respectively). This may render a more realistic flow path for groundwater to the main stream in each subbasin, but also result in a higher computational burden and parameter complexity. When delineating Upslope and Floodplain LSUs, we used the “DEM inversion” approach with default settings as indicated here (note this process can take several minutes):

Lakes:

This is optional. In the present SWAT+ setup, we included the vector map with 10 lakes and reservoirs, where the largest are Lakes Zebrus and Lake Svete. The delineation will then tailor LSU boundaries to the shoreline of the lakes and reservoirs.

Figure 2. Watershed, subbasins and streams delineated by SWAT+ with floodplain delineation (areas delineated as floodplains are indicated by light shaded areas). The outlets of subbasins are water sampling points and are indicated by blue triangles. The stream gauge station (also a water sampling point) at the Berze River (Berze-Balozi, at outlet of channel # 371) is indicated by red point.

### HRU creation

- Land use                      The CORINE Land Cover inventory from 2018.
- Soil                              The soil texture map from the national model.
- Slope classes                1 class.
- HRU filtering                10% threshold for land use, soil type and slope class.

**Final configuration:**

|                         |                                |
|-------------------------|--------------------------------|
| # Total watershed area: | 869.9 km <sup>2</sup>          |
| # Subbasins:            | 15                             |
| # LSUs:                 | 76 (excluding floodplain LSUs) |
| # HRUs                  | 724                            |

By utilizing the spatial datasets of Corine Land Cover 2018 and subsurface drainage systems in agricultural fields, which is part of the Digital Drainage Cadastre, the land use was classified into eight categories (Table 1). The arable lands, grasslands, and pastures were further subdivided based on dominant crop types using the "split" function (Tables 2 and 3). The share of dominant crop types was determined from the spatial datasets provided by the Rural Support Service of the Republic of Latvia. The land use codes (SWAT+ codes) were integrated into the plant.plt file and added to the plant database.

Soils were categorized into five classes based on their texture (Table 4). Soil characteristic parameters were assigned and detailed in the "usersoil.csv" file.

*Table 1. Land use of the Berze catchment as defined in the SWAT+ model*

| Land use                                | Area            |       | SWAT+ code  |
|---|-----------------|-------|-------------|
|   | km <sup>2</sup> | %     |             |
| Forests                                 | 340.9           | 39.2  | FRST        |

| Organic             | 5              | k           | 40.3             | 4.6            |
| <i>Total area</i>   |                |             | 869.9            | 100.0          |

The SWAT+ Editor was utilized for further model setup to define agricultural land management practices such as soil cultivation, fertilizer application, and harvest. Additionally, the information on 21 wastewater treatment plants was incorporated into the setup linking the wastewater treatment plants with the stream network and specifying characteristics of discharge and nutrient loading. The total annual load from the wastewater treatment plants accounts for 17,817 kg of nitrogen and 3,236 kg of phosphorus, with a total daily water discharge of 2,908 m<sup>3</sup>.

### Evaporation method

SWAT+ includes the choice of different evaporation methods including Hargreaves, Penman/Monteith, Priestly/Taylor or user defined time series. A study by Samadi (2017) suggested that Priestly/Taylor may provide best performance when simulating extreme events. Trolle and Nielsen (2020) found that Penmann/Montieth generally resulted in a better performance for the Vejle pilot area. Within the present study tests were performed at the initial stage. The results indicated that Penmann/Monteith outperforms other methods for the Berze catchment, therefore, this method was chosen in the present SWAT+ setup for this case study.

### Water abstractions

Not included in the SWAT+ setup for the Berze catchment.

### Inputs of external groundwater from areas outside topographical watershed

Not included in the SWAT+ setup for the Berze catchment.

## Calibration and validation

The model calibration process has commenced for the Berze catchment. Currently, our focus was orientated towards average long-term crop yields, components of water balance, and daily discharge at the outlet of the Berze River.

The calibration procedure was performed manually.

The calibration was performed by optimization of the coefficient of determination ( $R^2$ ) and the Nash-Sutcliffe Efficiency (NSE), which, like the  $R^2$ , is a correlative objective function. Percent bias, which is a residual objective function, was also evaluated. Classification of the performance was done by comparing performance against the criteria reviewed by Moriasi et al. (2015). The following time periods were used:

- Model warmup: 1. January 2005 - 31. December 2007 (three years)
- Calibration: 1. January 2010 - 31. December 2018 (nine years)
- Validation:
  - 1. January 2008 - 31. December 2009 (two years)
  - 1. January 2019 - 31. December 2022 (four years)

*Table 5. Parameters selected for calibration*

| Parameter                        | Change type | max          | min            | average |

[1] Classification according to Moriasi et al. (2015) noted in parenthesis.

**Figure 3.** Observed and simulated discharge for the Berze River, at the Berze-Balozsi gauge station (2008-2022) for the calibrated model. Calibration and validation periods are separated by red vertical lines.

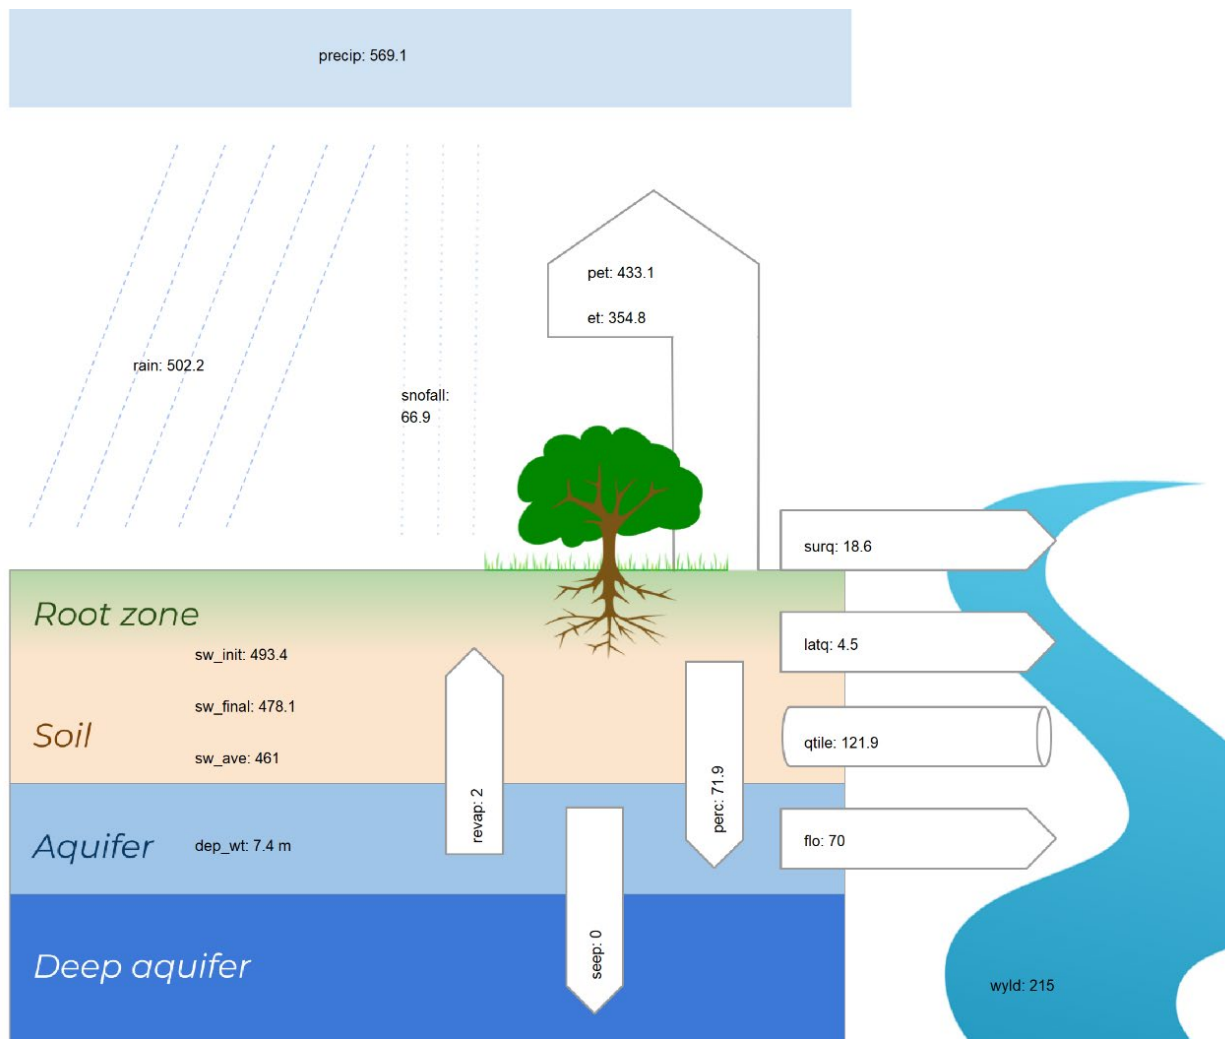

Figure 4. Key watershed-wide hydrology components simulated for period 2008-2022 (based on the calibrated model). Water balance components are given in mm and are abbreviated as follow: surq - surface runoff, latq - lateral flow, qtile - runoff from tile drainage systems, flo - groundwater flow, perc - percolation wyld - streamflow, precip - precipitation, pete - potential evapotranspiration, et - actual evapotranspiration, sw\_init, sw\_final and sw\_ave - initial, final and average soil water content respectively. (Figure is produced by R-script "SWATdoctR").

## Summary

A SWAT+ model was set up from scratch for the Berze catchment. The data used in the presented SWAT+ project are all available at national level, and therefore the SWAT+ approach used in this project can be applied all across Latvia. The SWAT+ model was calibrated on a daily time step, and produced generally satisfactory results for discharge at the outlet of the Berze catchment. Also, the results of simulated crop yields and representation of water balance components are satisfactory.
